Abstract: Before an engine can be scheduled in the Product Development cycle for inclusion in a vehicle, it must be calibrated in such a way that it satisfies a variety of regulatory tests over a range of conditions. The current engine calibration process involves conducting a design of experiments at a representative number of steady state points in order to satisfy all required regulatory tests; test engineers use a standard 16×16 grid with standard grid spacing and then conduct a design of experiments on a subset of those points - about 120 of them. This work explores how to reduce the engine calibration process time by finding the best 16×16 grid choice (i.e. the best spacing on both the engine speed and torque axes) and the minimum number of points on the grid to test in order to satisfy regulatory constraints around NO_x , particulate matter, noise, and fuel consumption. Our proposed method models the problem as a Binary Integer Program that simultaneously selects the best grid spacing and optimized number of points to test, while guaranteeing that all specified constraints hold. We present an example that demonstrates how we can reduce the number of necessary test points by approximately 56%.

1 INTRODUCTION

As vehicle emission and fuel economy standards continue to tighten, manufacturers respond by developing increasingly more complex engine systems with advanced control strategies. The process of calibrating such an engine (i.e. assigning the desired values to control parameters) quickly becomes a daunting task for calibration engineers. In the case of a modern internal combustion engine that may have six or more inputs (e.g. injection timings, injection quantities, intake manifold pressure, and exhaust gas recirculation rate), generating data for the calibration task is a time consuming and costly endeavor. If we consider the simple case where the response of the engine could be reasonably modeled with a quadratic function (i.e. each control factor can be understood by using three settings), and the engine speed and load regime (i.e. the range of engine rotational speed and available output torque) are each segmented by 16 grid quadrants, then the calibration engineer would be need to run $16^2 \times 6^3 = 256 \times 4,096 = 55,296$ test points: this is derived from the (number of quadrants)^{engine speed \times torque} \times (number of inputs)^{number of settings}. At roughly 5 minutes per test point, data collection alone would take over six months! Confound this with the fact that calibrations

must be developed for different operating conditions and engine operation modes, and the product development timeline quickly becomes uncompetitive.

There has been significant work using design of experiment (DoE) and mathematical optimization techniques to minimize the amount of input data needed for every given speed and load combination (e.g. (Yoshida et al., 2011), (Maloney, 2009), (Castagné et al., 2008), and (Langouët et al., 2008)): the goal is to reduce the number of input combinations to some fraction of the possible combination of inputs and settings (e.g. $6^3 = 4,096$ combinations when there are six inputs and three settings). However, this work does not address on which of the $16^2 = 256$ speed and load combinations (i.e. test points) a calibration engineer should focus their efforts, as it is not feasible to consider every combination. This selection of test points needs to be determined in such a way to satisfy testing of typical transient drive cycles needed to pass certification (i.e. the Environmental Protection Agency (EPA) Federal Test Procedure (FTP) 75 test cycle (EPA, 1977)).

Steady state (SS) engine development consists of maintaining constant speed and load for prolonged periods of time (e.g. five minutes or more). This is not, however, typical of how most vehicle owners operate their vehicles. Vehicles are usually driven in

enhance the computational efficiency A dynamic map is identified using the inverse optimal behaviour The map is shown to be capable of providing a minimized fuel consumption and generally meeting the demands of engine torque and air fuel ratio The control performance of this feedforward map is further improved by the addition of a closed loop controller An open loop compensator for torque control and a Smith predictor for air fuel ratio control are designed and shown to solve the issues of practical implementation on production engines A basic pseudo static engine based calibration is generated for comparative purposes and the resulting static map is implemented in order to compare the fuel consumption and torque and air fuel ratio control with that of the proposed dynamic calibration method Methods of optimal test signal design and parameter estimation for polynomial models are particularly detailed and studied in this thesis since polynomial models are frequently used in the process of dynamic calibration and control Because of their ease of implementation the input designs with different objective functions and optimization algorithms are discussed Novel design criteria which lead to an improved parameter estimation and output prediction method are presented and verified using identified models of a 1.6L Zetec engine developed from test data obtained on the Liverpool University Powertrain Laboratory Practical amplitude and rate constraints in engine experiments are considered in the optimization and optimal inputs are further validated to be effective in the black box modelling of the virtual engine An additional experiment of input design for a MIMO model is presented based on a weighted optimization method Besides the prediction error based estimation method a simulation error based estimation method is proposed This novel method is based on an unconstrained numerical optimization and any output fitness criterion can be used as the objective function The effectiveness is also evaluated in a black box engine modelling and parameter estimations with a better output fitness of a simulation model are provided [Statistics for Engine Optimization](#)

box model with intelligence to efficiently calibrate nonlinear systems without detailed knowledge of system dynamics The surrogate assisted optimization approach is an attractive way to reduce the total computational budget for obtaining optimal solutions This makes it special for its application to practical optimization problems requiring a large number of expensive evaluations The current research work focuses on the problem of performing engine calibration using the surrogate assisted optimization approach The objective is to find the trade off curve between engine efficiency in terms of brake specific fuel consumption BSFC and its NOx emissions by efficiently optimizing various control parameters The complete study is divided into three parts The first part deals with modifying the original algorithm for efficiently handling the practical system with measurement noise A new constrained handling algorithm is proposed for lower confidence bound LCB criteria that showed good performance for both deterministic and stochastic systems Furthermore two extensions based on the expected improvement EI criterion are proposed for handling stochastic multi objective problems After the methodology development for handling stochastic systems the second part validates their efficacy for performing the engine calibration in a simulation setting All three algorithms are compared to identify the best approach for its implementation on the actual engine experimental setup Three control parameters namely variable geometry turbocharger VGT vane position exhaust gas recirculating EGR valve position and the start of injection SOI are calibrated to obtain the trade off between engine fuel efficiency performance BSFC and NOx emissions within the constrained design space The simulation study identifies the lower confidence bound LCB criteria with the proposed constraint handling approach to work well in the stochastic setting compared with the other two extensions Therefore this approach is used for the experimental evaluation of the proposed surrogate assisted optimization for engine calibration Finally the third part is the experimental validation It is the first step towards automating the entire engine calibration process Experimental evaluations are performed on a 6.7L Ford diesel engine to validate the algorithm s efficacy Problems with different complexity are formulated and evaluated using the proposed approach Initially a simpler problem with two control variables is formulated to get the confidence to perform the experiments using the proposed algorithm Two variables EGR valve position and VGT vane positions are calibrated to obtain a trade off between engine efficiency BSFC and NOx emissions After observing promising results the study is concluded with a more complicated three control variable problem An external electrically assisted boosting device eBoost is added to the engine system to perform calibration Results showed improved engine performance using the eBoost with a significant reduction in calibration effort in terms of the number of experimental evaluations The study successfully demonstrated the application of the surrogate assisted optimization approach to a practical engine system and opened the door to automate the engine calibration process with reduced calibration efforts
