Chapter 4: Multivariate Probability Distribution

1. Joint Probability Distributions

Our study of random variables and their probability distributions in the preceding chapters is restricted to one–dimensional sample spaces, where we recorded outcomes of an experiment as values assumed by a single random variable. There will be situations, however, where we may find it desirable to record the simultaneous outcomes of several variables. For example:

1.   We might measure the amount of precipitate P and volume V of gas released from a controlled chemical experiment, giving rise to a two–dimensional sample space consisting of the outcomes (p, v).

2.   We might be interested in the hardness H and tensile strength T of cold–drawn copper, resulting in the outcomes (h, t).

3.   In a study to determine the likelihood of success in college based on high school data, we might use a three-dimensional sample space and record for each individual his or her aptitude test score, high school class rank, and grade-point average at the end of freshman year in college.

If X and Y are two discrete random variables, the probability distribution for their simultaneous occurrence can be represented by a function with values $f(x, y)$ for any pair of values (x, y) within the range of the random variables X and Y. This function is referred to as the joint probability distribution of X and Y.

Hence, in the discrete case,

$$f(x, y) = P(X = x, Y = y)$$

that is, the values $f(x, y)$ give the probability that outcomes x and y occur at the same time.

Definition 1.1
The function $f(x, y)$ is a joint probability distribution or probability mass function of the discrete random variables X and Y if

1. $f(x, y) \geq 0$ for all (x, y)

2. $\sum_x \sum_y f(x, y) = 1$

3. $P(X = x, Y = y) = f(x, y)$

For any region A in the xy plane, $P\left[(X, Y) \in A\right] = \sum\sum_A f(x, y)$
