Semantic View Re-creation for the Secure Monitoring of Virtual Machines
Martim Carbone, 2012 The insecurity of modern day software has created the need for security monitoring applications Two serious deficiencies are commonly found in these applications First the absence of isolation from the system being monitored allows malicious software to tamper with them Second the lack of secure and reliable monitoring primitives in the operating system makes them easy to be evaded A technique known as Virtual Machine Introspection attempts to solve these problems by leveraging the isolation and mediation properties of full system virtualization A problem known as semantic gap however occurs as a result of the low level separation enforced by the hypervisor This thesis proposes and investigates novel techniques to overcome the semantic gap advancing the state of the art on the syntactic and semantic view re creation for applications that conduct passive and active monitoring of virtual machines First we propose a new technique for reconstructing a syntactic view of the guest OS kernel s heap state by applying a combination of static code and dynamic memory analysis Our key contribution is the accuracy and completeness of our analysis We also propose a new technique that allows out of VM applications to invoke and securely execute API functions inside the monitored guest s kernel eliminating the need for the application to know details of the guest s internals Our key contribution is the ability to overcome the semantic gap in a robust and secure manner Finally we propose a new virtualization based event monitoring technique based on the interception of kernel data modifications Our key contribution is the ability to monitor operating

system events in a general and secure fashion
