

Cellular Respiration: Understanding It?

Cellular respiration is the process by which cells convert glucose and oxygen into energy (ATP) and carbon dioxide. It occurs in the mitochondria of eukaryotic cells and in the cytoplasm of prokaryotic cells. The process is divided into three main stages: glycolysis, the Krebs cycle, and the electron transport chain.

Glycolysis: This stage occurs in the cytoplasm and involves the breakdown of glucose into pyruvate. It consists of ten enzymatic steps, with the first five steps occurring in the cytosol and the last five in the mitochondria. Glycolysis produces four molecules of ATP and two molecules of pyruvate from one molecule of glucose.

The Krebs Cycle: Also known as the citric acid cycle, this stage occurs in the mitochondria. It involves the breakdown of pyruvate into carbon dioxide and the production of high-energy electron carriers (NADH and FADH₂). The cycle produces three molecules of NADH and one molecule of FADH₂ per pyruvate molecule.

The Electron Transport Chain: This stage occurs in the inner mitochondrial membrane. It involves the transfer of electrons from NADH and FADH₂ to oxygen, which is reduced to water. This process produces a large amount of ATP through oxidative phosphorylation.

Clinical Urography 3 Volume Set
